Outline

CARA Mission

- Purpose

- Complexity

- Consequence

Conjunction Identification

- Volumetric Screening

Conjunction Analysis

- Risk Measures

- 2D P_C

- 3D P_C

- Monte Carlo

CARA in Theory

Mission Statement:

To take prudent measures, at reasonable cost, to enhance safety of flight, without placing an undue burden on mission operations

CARA in Practice

Inputs:

- ▶ Ephemeris data from cooperating missions.
- ▶ Catalog of tracked earth-orbiting objects from Combined Space Operations Center (CSpOC).

Outputs:

- ▶ Alerts to protected missions on high interest events (HIEs).
- ▶ Advisories for protected missions on risk mitigations for HIEs.
 - ▶ Hopefully avoid more Kosmos-Iridium incidents.

Kepler Orbits

$$\ddot{R} = \ddot{R}_{2B} = \frac{Gm_{\text{other}}}{||R||^3} R$$

- ▶ Solution known since Kepler and Newton.
 - ▶ Must be a conic section.
 - ▶ If closed, then ellipse.
- ▶ A star holds its course and its aim. . . returns and returns. . . and is always the same
 - ▶ *Mais non*

Perturbation: Third Bodies

$$\ddot{\mathbf{R}} = \ddot{\mathbf{R}}_{2B} + \ddot{\mathbf{R}}_{PM}$$

- ▶ Gravity is a universal force.
- ▶ Lots of non-earth mass out there
 - ▶ Luna
 - ▶ Sol
 - ▶ Uncounted others (fortunately negligible)
- ▶ Particularly relevant for higher-altitude orbits.

Perturbation: Non-Sphericity

$$\ddot{\mathbf{R}} = \ddot{\mathbf{R}}_{2B} + \ddot{\mathbf{R}}_{PM} + \ddot{\mathbf{R}}_{NS}$$

- ▶ $\ddot{\mathbf{R}}_{2B}$ uses point-mass equations
 - ▶ Works for points
 - ▶ Works for spheres (shell theorem)
- ▶ Earth is neither
 - ▶ Tidal forces (order meters)
 - ▶ Centrifugal forces (order kilometers)

Non-Sphericity: Oblation

Gross exaggeration: cylindrical Earth

Equatorial gravity increases. Polar gravity decreases.

Perturbation: Indirect Oblation

$$\ddot{\mathbf{R}} = \ddot{\mathbf{R}}_{2B} + \ddot{\mathbf{R}}_{PM} + \ddot{\mathbf{R}}_{NS} + \ddot{\mathbf{R}}_{IO}$$

- ▶ Earth is not an inertial reference frame
 - ▶ Has its own orbit around Sol
 - ▶ Yanked around by Luna inside that orbit
- ▶ “Shaky Camera” effect

Perturbation: Drag

$$\ddot{\mathbf{R}} = \ddot{\mathbf{R}}_{2B} + \ddot{\mathbf{R}}_{PM} + \ddot{\mathbf{R}}_{NS} + \ddot{\mathbf{R}}_{IO} + \ddot{\mathbf{R}}_D$$

- ▶ Drag equation: $F_D = \frac{1}{2}\rho v^2 C_D A$
- ▶ Scales by
 - ▶ Object shape and orientation (C_D, A).
 - ▶ Square of object velocity v^2 .
 - ▶ Atmospheric density ρ , drops exponentially with altitude.
- ▶ LEO objects (altitude \leq 2000 km) are low and fast
 - ▶ experience non-negligible drag
- ▶ Bonus: non-periodic and non-conservative.

Perturbation: Solar Radiation Pressure

$$\ddot{\mathbf{R}} = \ddot{\mathbf{R}}_{2B} + \ddot{\mathbf{R}}_{PM} + \ddot{\mathbf{R}}_{NS} + \ddot{\mathbf{R}}_{IO} + \ddot{\mathbf{R}}_D + \ddot{\mathbf{R}}_{SRP}$$

- ▶ $\gamma := \sqrt{\frac{c^2}{c^2 - v^2}}$
- ▶ $p = \gamma mv$
- ▶ photons: $m \rightarrow 0, \gamma \rightarrow \infty$
 - ▶ $p \rightarrow ?$
 - ▶ God's math: $p = \frac{h}{\lambda}$
- ▶ Absorbing and emitting light imparts momentum
 - ▶ Sunlight never stops: SRP
 - ▶ Most impactful on higher altitude orbits
 - ▶ Non-periodic and non-conservative

Perturbation: Thrust

$$\ddot{\mathbf{R}} = \ddot{\mathbf{R}}_{2B} + \ddot{\mathbf{R}}_{PM} + \ddot{\mathbf{R}}_{NS} + \ddot{\mathbf{R}}_{IO} + \ddot{\mathbf{R}}_D + \ddot{\mathbf{R}}_{SRP} + \ddot{\mathbf{R}}_T$$

- ▶ Orbital payloads commonly come equipped with maneuvering thrusters
 - ▶ Chemical burns (fast, short)
 - ▶ Electric propulsion (slow, long)
- ▶ Good news: allows for doing something about predicted collisions
- ▶ Bad news: Non-periodic, non-conservative, AND non-physical(-ish)

Perturbation Impacts

- ▶ Low-to-medium fidelity diff-eqs can be solved analytically
 - ▶ E.g. Brouwer models, SGP4/SDP4
- ▶ High-fidelity generally resort to numerical integration
 - ▶ E.g. NORAD Special Perturbations (SP)
- ▶ Low- and high-fidelity models can diverge significantly, rapidly
 - ▶ By kilometers
 - ▶ Within a few orbital periods (i.e. hours)

Mission Safety

$$E(\text{Cost}(X)) = P(X) \cdot \text{Cost}(X)$$

- ▶ Plausible $\text{Cost}(X)$: 100 million USD
- ▶ Plausible $P(X)$: $2e-4$
- ▶ $E(\text{Cost}(X)) = 2 \cdot 10^{-4} \cdot 10^8 = 20000$ USD
 - ▶ Might be worth mitigating
 - ▶ Although, $\sim 85\%$ of likely-lethal conjunctors aren't even tracked ...

Domain Safety I

- ▶ Orbit contention is self-reinforcing
 - ▶ More objects means more conjunctions
 - ▶ More conjunctions means more collisions
 - ▶ More collisions means more objects
- ▶ Critical density → runaway, sustained fragmentation
 - ▶ Kessler syndrome
- ▶ Sub-critical density increases still increase hazard to ecosystem

Domain Safety II

- ▶ Vested public interest in controlling flux
- ▶ Must avoid collisions, especially between large objects
 - ▶ Debris potential strongly linked to object size
 - ▶ Largest objects are best tracked
 - ▶ Objects follow a power-law distribution: many, many small pieces, comparatively few large

Outline

CARA Mission

- Purpose

- Complexity

- Consequence

Conjunction Identification

- Volumetric Screening

Conjunction Analysis

- Risk Measures

- 2D P_C

- 3D P_C

- Monte Carlo

Conjunction Screening

- ▶ Before a conjunction can be analyzed it must be identified
 - ▶ Want to know the time of closest approach (TCA)
 - ▶ and of course the conjunctors' states at TCA
- ▶ Technically not a CARA responsibility
 - ▶ Screening computed for CARA by CSpOC using COMBO (Computation of Miss Between Orbits).
 - ▶ Operates on a “flying-ellipsoid” volumetric screening paradigm.

Volumetric Screening

Volumetric Screening

procedure SCREENCONJUNCTIONS

for $p, s, t \in \text{Primaries} \times \text{Secondaries} \times \text{Time Slices}$ **do**

$V \leftarrow$ ellipse around $p(t)$

if $s(t).\text{pos} \notin V$ **then**

continue

$d(\tau) := ||p(\tau).\text{pos} - s(\tau).\text{pos}||$

if $\text{sign}(d'(t)) = \text{sign}(d'(t + \Delta t))$ **then**

continue

$t^* \leftarrow \text{argmin}_{[t, t+\Delta t]} d$

Emit (p, s, t^*)

Outline

CARA Mission

- Purpose

- Complexity

- Consequence

Conjunction Identification

- Volumetric Screening

Conjunction Analysis

- Risk Measures

- 2D P_C

- 3D P_C

- Monte Carlo

Standoff Distance

- ▶ Most intuitive measure of safety
 - ▶ If we are far apart, of course we aren't touching.
 - ▶ Implicitly part of volumetric screening regimes.
- ▶ Difficult to map distance onto risk.
 - ▶ How far apart is far? Meters? Kilometers?
- ▶ Cannot capture uncertainty
 - ▶ What if our measurements of a satellite's state are known to be imprecise?
- ▶ Tendency toward conservatism
 - ▶ sometimes desirable, e.g. around human space flight assets

Probability of Collision

- ▶ Most commonly used measure of safety.
- ▶ Answers the challenges with standoff distance
 - ▶ Maps naturally to risk.
 - ▶ Captures and describes uncertainty and imprecision.
 - ▶ Allows for mindfully tuned risk postures.
- ▶ But! Can suffer from probability dilution.
 - ▶ Space is big. Really big. Really, really big.
 - ▶ Rubbish measurements $\Rightarrow P_C \approx 0$.
 - ▶ Probability is “diluted” across space.

Severity Estimation

- ▶ For the domain:
 - ▶ Different collisions create different amounts of debris.
 - ▶ EVOLVE: empirically determined model mapping relative masses and velocities to expected fragmentation count.
 - ▶ Basic rules: fast is bad, heavy is bad.
 - ▶ Of course, ultimately dependent on O/Os to maneuver/mitigate.
- ▶ For O/Os:
 - ▶ Everything is moving too damned fast
 - ▶ Everything is too damned expensive
 - ▶ A hit is a hit is a hit is a bad time

Naive P_C

$$\int \int f(S_1, S_2) \mathbb{I}(\text{collision} | S_1, S_2) dS_1 dS_2$$

- ▶ That's a 12-dimensional integral.
- ▶ $\mathbb{I}(\text{collision} | S_1, S_2)$ is a nightmare function.
- ▶ Let's make some simplifying assumptions

2D P_C : Assumptions

1. State position vectors $R_1 \sim \mathcal{N}(\bar{R}_1, C_1)$, $R_2 \sim \mathcal{N}(\bar{R}_2, C_2)$
2. $R_1 \perp R_2$
3. Velocity uncertainty is negligible
4. Position uncertainty is stable throughout the encounter
5. Relative motion is linear throughout the encounter
6. Both objects are spheres

2D P_C

Core idea: Don't think about two objects, think about the distance separating them. More precisely, let

$$R_{\text{miss}} := R_2 - R_1$$

We wish to integrate

$$\int f_{\text{miss}}(R) \mathbb{I}(\text{collision}|R) dR$$

2D P_C 2D P_C

$$\int f_{\text{miss}}(R) \mathbb{I}(\text{collision}|R) dR$$

Recall: $R_1 \perp R_2$, both Gaussian. So

$$R_{\text{miss}} \sim \mathcal{N}(\bar{R}_2 - \bar{R}_1, C_2 - C_1)$$

f_{miss} is just ϕ !

2D P_C 2D P_C

$$\int f_{\text{miss}}(R) \mathbb{I}(\text{collision}|R) dR$$

Linear motion, spherical objects. Collision iff $\exists t \in \mathbb{R}$ s.t.

$$||R_{\text{miss}} + v_{\text{miss}} \cdot t|| < r$$

That's a cylinder!

2D P_C

Observe: cylinder is infinite. Rotate our z-axis to align with it, and it will marginalize to 1.

A little final massaging and we arrive at a numerical-quadrature-friendly integral.

$$P_C = \frac{1}{\sqrt{\det(2\pi C)}} \int \int_A \exp\left(-\frac{r^T C^{-1} r}{2}\right) dx dy$$

Hyperkinetic Assumptions

- ▶ 2D P_C treated conjunctors like a pair of bullets
- ▶ Pretty good model when relative velocity is high, encounter is short
- ▶ Not all close approaches occur at high (relative) velocity, though
- ▶ Can we do better?

3D P_C

What happens if we trace our miss vector through the encounter?

$$\int P(\text{conjunctions touching at } t) dt$$

That's actually N_C , the expected number of collisions, but close enough.

3D P_C

$$P(\text{conjunctions touching at } t) = P(\|R_{\text{miss}}(t)\| = r)$$

- ▶ The integrand is a surface integral over a sphere!
 - ▶ Total integration dimension: 3
 - ▶ Curse of dimensionality remains weak
- ▶ Can we compute and integrate $R_{\text{miss}}(t)$?
 - ▶ Yes, with two-body equations of motion... but the math is kind of involved.
 - ▶ Please read the full pub if interested.

Motivation

- ▶ All this integration, it's making my head hurt.
- ▶ Even the fancy 3D P_C variant had to make simplifying assumptions.
- ▶ This is a stochastic process, let's try modeling it stochastically.

From-Epoch MC

```
procedure FROMEPOCHMC(primOD, secOD, trials)  
  hits  $\leftarrow$  0  
  for  $i \in [0, \dots, \textit{trials})$  do  
     $p \leftarrow$  draw from primOD  
     $s \leftarrow$  draw from secOD  
    if  $p.\text{propagate}()$  collides with  $s.\text{propagate}()$  then  
      hits  $\leftarrow$  hits + 1  
  return  $\frac{\textit{hits}}{\textit{trials}}$ 
```

From-Epoch MC

- ▶ No simplifying assumptions! Estimate is as good as
 - ▶ Our orbit propagation algorithm
 - ▶ The number of trials we run
- ▶ Heinously expensive, though
 - ▶ Millions and millions of trials
 - ▶ Each trial doing high-fidelity numerical ODE solving from epoch up through TCA
- ▶ Most useful to prove out the accuracy of other algorithms.

From-TCA MC

```
procedure FROMTCAMC(primTCA, secTCA, trials)  
  hits  $\leftarrow$  0  
  for  $i \in [0, \dots, \textit{trials}]$  do  
     $p \leftarrow$  draw from primTCA  
     $s \leftarrow$  draw from secTCA  
    if  $p.\text{propForward}()$  collides with  $s.\text{propForward}()$  then  
      hits  $\leftarrow$  hits + 1  
    else if  $p.\text{propBack}()$  collides with  $s.\text{propBack}()$  then  
      hits  $\leftarrow$  hits + 1  
  return  $\frac{\textit{hits}}{\textit{trials}}$ 
```

From-TCA MC

- ▶ Faster than From-Epoch
 - ▶ Only need to propagate motion around the encounter
 - ▶ Shorter motion-prop window means lower fidelity propagation schemes can be used.
- ▶ Depends on assumptions about the shape of propagated uncertainty
 - ▶ Not really a practical issue if we're careful to sample in curvilinear coordinates.
- ▶ Still much slower than analytic methods.
 - ▶ Empirically not much better results
 - ▶ Not frequently used in CARA in practice
