**CARA Mission** 

Purpose

Complexity

Consequence

00000000

## CARA in Theory

#### Mission Statement:

To take prudent measures, at reasonable cost, to enhance safety of flight, without placing an undue burden on mission operations

#### CARA in Practice

#### Inputs:

- Ephemeris data from cooperating missions.
- Catalog of tracked earth-orbiting objects from Combined Space Operations Center (CSpOC).

#### Outputs:

- Alerts to protected missions on high interest events (HIEs).
- Advisories for protected missions on risk mitigations for HIEs.
  - Hopefully avoid more Kosmos-Iridium incidents.

•00000000

## Kepler Orbits

$$\ddot{R} = \ddot{R}_{2B} = \frac{Gm_{\text{other}}}{||R||^3}R$$

- Solution known since Kepler and Newton.
  - Must be a conic section.
  - If closed, then ellipse.
- A star holds its course and its aim... returns and returns...and is always the same
  - Mais non

#### Perturbation: Third Bodies

$$\ddot{R} = \ddot{R}_{2B} + \ddot{R}_{PM}$$

- Gravity is a universal force.
- Lots of non-earth mass out there
  - Luna
  - ► Sol
  - Uncounted others (fortunately negligible)
- Particularly relevant for higher-altitude orbits.

000000000

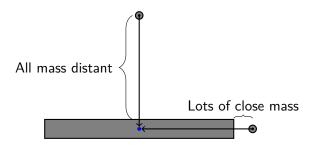

### Perturbation: Non-Sphericity

$$\ddot{R} = \ddot{R}_{2B} + \ddot{R}_{PM} + \ddot{R}_{NS}$$

- R<sub>2B</sub> uses point-mass equations
  - Works for points
  - Works for spheres (shell theorem)
- Farth is neither
  - Tidal forces (order meters)
  - Centrifugal forces (order kilometers)

## Non-Sphericity: Oblation

Gross exaggeration: cylindrical Earth

Equatorial gravity increases. Polar gravity decreases.

000000000

#### Perturbation: Indirect Oblation

$$\ddot{R} = \ddot{R}_{2B} + \ddot{R}_{PM} + \ddot{R}_{NS} + \ddot{R}_{IO}$$

- Earth is not an inertial reference frame
  - Has its own orbit around Sol
  - Yanked around by Luna inside that orbit
- "Shaky Camera" effect

00000000

## Perturbation: Drag

$$\ddot{R} = \ddot{R}_{2B} + \ddot{R}_{PM} + \ddot{R}_{NS} + \ddot{R}_{IO} + \ddot{R}_{D}$$

- ► Drag equation:  $F_D = \frac{1}{2}\rho v^2 C_D A$
- Scales by
  - ightharpoonup Object shape and orientation  $(C_D, A)$ .
  - ▶ Square of object velocity  $v^2$ .
  - Atmospheric density *rho*, drops exponentially with altitude.
- ▶ LEO objects (altitude ¡ 2000 km) are low and fast
  - experience non-negligible drag
- Bonus: non-periodic and non-conservative.

000000000

#### Perturbation: Solar Radiation Pressure

$$\ddot{R} = \ddot{R}_{2B} + \ddot{R}_{PM} + \ddot{R}_{NS} + \ddot{R}_{IO} + \ddot{R}_{D} + \ddot{R}_{SRP}$$

- $\triangleright$   $p = \gamma mv$
- **h** photons:  $m \to 0, \gamma \to \infty$ 
  - $\triangleright p \rightarrow ?$ 
    - God's math:  $p = \frac{h}{\lambda}$
- Absorbing and emitting light imparts momentum
  - Sunlight never stops: SRP
  - Most impactful on higher altitude orbits
  - Non-periodic and non-conservative

000000000

#### Perturbation: Thrust

$$\ddot{R} = \ddot{R}_{2B} + \ddot{R}_{PM} + \ddot{R}_{NS} + \ddot{R}_{IO} + \ddot{R}_{D} + \ddot{R}_{SRP} + \ddot{R}_{T}$$

- Orbital payloads commonly come equipped with maneuvering thrusters
  - Chemical burns (fast, short)
  - Electric propulsion (slow, long)
- Good news: allows for doing something about predicted collisions
- Bad news: Non-periodic, non-conservative, AND non-physical(-ish)

00000000

### Perturbation Impacts

- Low-to-medium fidelity diff-eqs can be solved analytically
  - ► E.g. Brouwer models, SGP4/SDP4
- High-fidelity generally resort to numerical integration
  - E.g. NORAD Special Perturbations (SP)
- Low- and high-fidelity models can diverge significantly, rapidly
  - Bv kilometers
  - Within a few orbital periods (i.e. hours)

•00

CARA Mission

# Mission Safety

$$E(\mathsf{Cost}(X)) = P(X) \cdot \mathsf{Cost}(X)$$

- Plausible Cost(X): 100 million USD
- ▶ Plausible P(X): 2e-4
- $E(Cost(X)) = 2 \cdot 10^{-4} \cdot 10^8 = 20000 \text{ USD}$ 
  - Might be worth mitigating
  - ightharpoonup Although,  $\sim 85\%$  of likely-lethal conjunctors aren't even tracked ....

## Domain Safety I

- Orbit contention is self-reinforcing
  - ► More objects means more conjunctions
  - More conjunctions means more collisions
  - More collisions means more objects
- lacktriangle Critical density ightarrow runaway, sustained fragmentation
  - Kessler syndrome
- Sub-critical density increases still increase hazard to ecosystem

## Domain Safety II

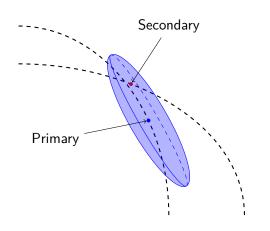

- Vested public interest in controlling flux
- Must avoid collisions, especially between large objects
  - Debris potential strongly linked to object size
  - Largest objects are best tracked
  - Objects follow a power-law distribution: many, many small pieces, comparatively few large

Conjunction Identification Volumetric Screening

# Conjunction Screening

- Before a conjunction can be analyzed it must be identified
  - Want to know the time of closest approach (TCA)
  - and of course the conjunctors' states at TCA
- Technically not a CARA responsibility
  - Screening computed for CARA by CSpOC using COMBO (Computation of Miss Between Orbits).
  - Operates on a "flying-ellipsoid" volumetric screening paradigm.

# Volumetric Screening

# Volumetric Screening

```
procedure ScreenConjunctions
for p, s, t \in Primaries \times Secondaries \times Time Slices do
     V \leftarrow \text{ellipse around } p(t)
     if s(t).pos \notin V then
          continue
     d(\tau) := ||p(\tau).\mathsf{pos} - s(\tau).\mathsf{pos}||
     if sign(d'(t)) = sign(d'(t + \Delta t)) then
          continue
     t^* \leftarrow \operatorname{argmin}_{[t,t+\Delta t]} d
     Emit (p, s, t^*)
```

Conjunction Analysis

#### Conjunction Analysis

Risk Measures

 $2D P_C$ 

 $3D P_C$ 

Monte Carlo

#### Standoff Distance

- Most intuitive measure of safety
  - If we are far apart, of course we aren't touching.
  - Implicitly part of volumetric screening regimes.
- Difficult to map distance onto risk.
  - How far apart is far? Meters? Kilometers?
- Cannot capture uncertainty
  - What if our measurements of a satellite's state are known to be imprecise?

Conjunction Analysis

- Tendency toward conservatism
  - sometimes desirable, e.g. around human space flight assets

## Probability of Collision

- Most commonly used measure of safety.
- Answers the challenges with standoff distance
  - Maps naturally to risk.
  - Captures and describes uncertainty and imprecision.

Conjunction Analysis

- Allows for mindfully tuned risk postures.
- But! Can suffer from probability dilution.
  - Space is big. Really big. Really, really big.
  - Rubbish measurements  $\Rightarrow P_C \approx 0$ .
  - Probability is "diluted" across space.

## Naive $P_C$

$$\int \int f(S_1, S_2) \mathbb{I}(\text{collision}|S_1, S_2) dS_1 dS_2$$

Conjunction Analysis

•000000

- That's a 12-dimensional integral.
- ▶  $\mathbb{I}(\text{collision}|S_1, S_2)$  is a nightmare function.
- Let's make some simplifying assumptions

## 2D $P_C$ : Assumptions

1. State position vectors  $R_1 \sim \mathcal{N}(\bar{R_1}, C_1), R_2 \sim \mathcal{N}(\bar{R_2}, C_2)$ 

Conjunction Analysis

000000

- 2.  $R_1 \perp R_2$
- 3. Velocity uncertainty is negligible
- 4. Position uncertainty is stable throughout the encounter
- 5. Relative motion is linear throughout the encounter
- 6. Both objects are spheres

#### $2D P_C$

Core idea: Don't think about two objects, think about the distance separating them. More precisely, let

Conjunction Analysis

0000000

$$R_{\mathsf{miss}} := R_2 - R_1$$

We wish to integrate

$$\int f_{\mathsf{miss}}(R) \mathbb{I}(\mathsf{collision}|R) dR$$

#### $2D P_{C}$

$$\int f_{\mathsf{miss}}(R) \mathbb{I}(\mathsf{collision}|R) dR$$

Conjunction Analysis

0000000

Recall:  $R_1 \perp R_2$ , both Gaussian. So

$$\textit{R}_{miss} \sim \mathcal{N}(\bar{\textit{R}_{2}} - \bar{\textit{R}_{1}}, \textit{C}_{2} - \textit{C}_{1})$$

 $f_{\rm miss}$  is just  $\phi!$ 

#### $2D P_C$

$$\int f_{\mathsf{miss}}(R) \mathbb{I}(\mathsf{collision}|R) dR$$

Conjunction Analysis

0000000

Linear motion, spherical objects. Collision iff  $\exists t \in \mathbb{R}$  s.t.

$$||R_{\mathsf{miss}} + v_{\mathsf{miss}} \cdot t|| < r$$

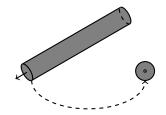

That's a cylinder!

$$( ) \qquad -t \longleftrightarrow +t \qquad ( )$$

## $2D P_C$

Rotate coordinates to align cylinder with z-axis.

Conjunction Analysis

oo 00000●0

Cylinder is infinite: z-axis marginalizes to 1.

#### $2D P_{C}$

Integral form after massaging:

$$P_C = \frac{1}{\sqrt{\det(2\pi C)}} \int \int_A \exp\left(-\frac{r^T C^{-1} r}{2}\right) dx dy$$

Conjunction Analysis

000000

Not fully analytic, but quite amenable to numerical quadrature.

### Hyperkinetic Assumptions

- ▶ 2D P<sub>C</sub> treated conjunctors like a pair of bullets
- Pretty good model when relative velocity is high, encounter is short

Conjunction Analysis

- Not all close approaches occur at high (relative) velocity, though
- Can we do better?

### 3D $P_{c}$

What happens if we trace our miss vector through the encounter?

Conjunction Analysis

$$\int P(\text{conjunctors touching at } t)dt$$

That's actually  $N_C$ , the expected number of collisions, but close enough.

#### 3D $P_{c}$

CARA Mission

$$P(\text{conjunctors touching at } t) = P(||R_{\text{miss}}(t)|| = r)$$

Conjunction Analysis

- ▶ The integrand is a surface integral over a sphere!
  - Total integration dimension: 3
  - Curse of dimensionality remains weak
- $\triangleright$  Can we compute and integrate  $R_{\text{miss}}(t)$ ?
  - Yes, with two-body equations of motion... but the math is kind of involved.
  - Please read the full pub if interested.

#### Motivation

- All this integration, it's making my head hurt.
- $\triangleright$  Even the fancy 3D  $P_C$  variant had to make simplifying assumptions.
- This is a stochastic process, let's try modeling it stochastically.

Conjunction Analysis

•0000

## From-Epoch MC

```
procedure From EpochMC(primOD, secOD, trials)
hits \leftarrow 0
for i \in [0, ..., trials) do
     p \leftarrow \text{draw from } primOD
     s \leftarrow \text{draw from } secOD
     if p.propagate() collides with s.propagate() then
         hits \leftarrow hits + 1
return \frac{hits}{trials}
```

Conjunction Analysis

00000

## From-Epoch MC

- No simplifying assumptions! Estimate is as good as
  - Our orbit propagation algorithm
  - The number of trials we run
- Heinously expensive, though
  - Millions and millions of trials
  - Each trial doing high-fidelity numerical ODE solving from epoch up through TCA

Conjunction Analysis

Most useful to prove out the accuracy of other algorithms.

#### From-TCA MC

```
procedure FromTCAMC(primTCA, secTCA, trials)
hits \leftarrow 0
for i \in [0, ..., trials) do
    p \leftarrow \text{draw from } primTCA
    s \leftarrow \text{draw from } secTCA
    if p.propForward() collides with s.propForward() then
        hits \leftarrow hits + 1
    else if p.propBack() collides with s.propBack() then
        hits \leftarrow hits + 1
return
```

Conjunction Analysis

#### From-TCA MC

- Faster than From-Epoch
  - Only need to propagate motion around the encounter
  - Shorter motion-prop window means lower fidelity propagation schemes can be used.

Conjunction Analysis

- Depends on assumptions about the shape of propagated uncertainty
  - Not really a practical issue if we're careful to sample in curvilinear coordinates.
- Still much slower than analytic methods.
  - Empirically not much better results
  - Not frequently used in CARA in practice

Risk Remediation Maneuver Planning

## **HIE Response**

Two choices for dealing with an HIE.

- 1. Change course
  - Costs fuel/reaction mass.
  - Generally cheaper the earlier an orbit is modified.
- Wait and see
  - Most HIEs come to nothing
  - Can self-resolve "early enough" as conjunction nears and uncertainty drops off.

Common pattern: plan maneuver immediately in response to HIE, then abort if HIE resolves before the commit point.

## Maneuver Trade Space

- Several knobs to turn when modifying trajectory
  - Burn intensity
  - Burn timing
  - Satellite orientation (differential drag)
- CARA maintains analysis tools for mapping possible maneuvers to expected  $P_C$  post-maneuver.
  - Not very well documented in the public domain...
- Allows us to mitigate the risk to the primary from this particular secondary.
- What about all the other possible conjunctors?

#### Maneuver Validation

- Space is big.
- The lane we plan to swerve into is *probably* open.
- Approach: Plan the remediation in isolation, then pass the planned orbit back into the next round of conjunction screening.
  - If no new HIEs crop up, we're good.
  - Else, try planning a different maneuver.
